

PRODUCT DATA SHEET

N-Dodecanoyl-D-erythro-sphingosine

Catalog number: 1936

Synonyms: N-C12:0-D-erythro-Ceramide

Source: synthetic

Solubility: chloroform, ethanol, DMSO, DMF

CAS number: N/A

Molecular Formula: C₃₀H₅₉NO₃

Molecular Weight: 482

Storage: -20°C

Purity: TLC: >98%; identity confirmed by MS

TLC System: chloroform/methanol 90:10

Appearance: solid

Application Notes:

This N-Dodecanoyl-D-erythro-sphingosine is ideal as a standard and for biological studies. Ceramide is a fatty acid amide of sphingosine that has many important biological functions and is the precursor for many complex glycosphingolipids. Ceramide functions as a precursor in the synthesis of sphingomyelin, glycosphingolipids, and of free sphingosine and fatty acids. The sphingosine can be phosphorylated to form sphingosine-1-phosphate. Two of ceramide's metabolites, sphingosine-1-phosphate and glucosylceramide, produce cell proliferation and other cellular functions.¹ Ceramide exerts numerous biological effects, including induction of cell maturation, cell cycle arrest, terminal cell differentiation, cell senescence, and cell death.² Because of these effects ceramide has been investigated for its use in cancer treatment and many potential approaches to cancer therapy have been presented.³ Other effects include producing reactive oxygen in mitochondria (followed by apoptosis) and stimulating phosphorylation of certain proteins (especially mitogen activated protein). It also stimulates some protein phosphatases (especially protein phosphatase 2A) making it an important controller of protein activity. In contrast to long chain ceramides short chain ceramides, such as N-octanoyl-sphingosine, can pass thru the cell membrane. This allows short chain ceramides to be used to induce apoptosis or necrosis in cancer cells.⁴
